## Proportionate Share Calculation Example

## Proposed ABC Store on an Existing 4-Lane Road

## Existing Capacity $=2,000$ vehicles per hour

Existing Volume $=1,900$ vehicles per hour (under capacity)

ABC Store Generates $=300$ vehicles per hour
Roadway volume with $A B C$ Store Traffic $=1,900+300=2,200$ vehciles per hour (over capacity)
That means the exiting 4-Lane roadway will fail. Road needs to be widened to 6-Lanes

Improved roadway (6-Lane) Capacity $=3000$ vehicles per hour
Capacity created $=3000-2000=1000$ vehciles per hour
Of this additional capacity, ABC Store will be using only 200 (note that out of a trip generation of 300 vehicles, the first 100 trips coule be accommodated on the existing roadway before the roadway is over capacity)

So, the Prop Share for $A B C$ Store is $=$
Project's Trip Contribution
Capcity Created from Improvement
$=\quad 200$
1000
$=20 \%$ of total cost of widening from 4 lanes to 6 lanes

With ABC Store $=2,200$

Existing 4-Lane Capacity=2,000

Existing Volume $=1,900$

## Baseline

Prop Share $=(2,200-2,000) /(3,000-2,000)=20 \%$
